# Chapter 1

## Mathematical Special Functions

### 1.1 Introduction and History

The first significant library upgrade on the road to C++2011, [TR1](#), included a set of 23 mathematical functions that significantly extended the standard transcendental functions inherited from C and declared in `<cmath>`.

Although most components from TR1 were eventually adopted for C++11 these math functions were left behind out of concern for implementability. The math functions were published as a separate international standard [IS 29124 - Extensions to the C++ Library to Support Mathematical Special Functions](#).

For C++17 these functions were incorporated into the main standard.

### 1.2 Contents

The following functions are implemented in namespace `std`:

- [assoc\\_laguerre](#) - Associated Laguerre functions
- [assoc\\_legendre](#) - Associated Legendre functions
- [beta](#) - Beta functions
- [comp\\_ellint\\_1](#) - Complete elliptic functions of the first kind

The hypergeometric functions were stricken from the TR29124 and C++17 versions of this math library because of implementation concerns. However, since they were in the TR1 version and since they are popular we kept them as an extension in namespace `__gnu_cxx`:

## 1.3 General Features

### 1.3.1 Argument Promotion

The arguments supplied to the non-suffixed functions will be promoted according to the following rules:

1. If any argument intended to be floating point is given an integral value That integral value is promoted to double.
2. All floating point arguments are promoted up to the largest floating point precision among them.

### 1.3.2 NaN Arguments

If any of the floating point arguments supplied to these functions is invalid or NaN (`std::numeric_limits<Tp>::quiet_` ← NaN), the value NaN is returned.

## 1.4 Implementation

We strive to implement the underlying math with type generic algorithms to the greatest extent possible. In practice, the functions are thin wrappers that dispatch to function templates. Type dependence is controlled with `std::numeric_limits` and functions thereof.

We don't promote `float` to `double` or `double` to `long double` reflexively. The goal is for `float` functions to operate more quickly, at the cost of `float` accuracy and possibly a smaller domain of validity. Similarly, `long double` should give you more dynamic range and slightly more precision than `double` on many systems.

## 1.5 Testing

These functions have been tested against equivalent implementations from the [Gnu Scientific Library](http://www.gnu.org/software/libc/), [GSL](http://www.gnu.org/software/gsl/) and [Boost](http://www.boost.org/doc/libs/1_60_0/libs/math/doc/html/index.html) and the ratio

$$\frac{|f - f_{test}|}{|f_{test}|}$$

is generally found to be within  $10^{-15}$  for 64-bit double on linux-x86\_64 systems over most of the ranges of validity.

**Todo** Provide accuracy comparisons on a per-function basis for a small number of targets.

### 7.2.2 Function Documentation

**7.2.2.1** `template<typename _Tp> __gnu_cxx::__promote<_Tp>::__type std::assoc_laguerre ( unsigned int __n, unsigned int __m, _Tp __x ) [inline]`

where  $(\alpha)_n$  is the Pochhammer symbol and  ${}_1F_1(a; c; x)$  is the confluent hypergeometric function.

The associated Laguerre polynomial is defined for integral degree  $\alpha = m$  by:

$$L_n^m(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x)$$

where the Laguerre polynomial is defined by:

$$L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x})$$

This function computes the Airy function  $Ai(z)$  and its first derivative in the complex  $z$ -plane.

The algorithm used exploits numerous representations of the Airy function and its derivative. The representations are recorded here for reference:

$$(1a) Ai(z) = \frac{\sqrt{z}}{3} (I_{-1/3}(\zeta) - I_{1/3}(\zeta))$$

$$(1b) Bi(z) = \sqrt{\frac{z}{3}} (I_{-1/3}(\zeta) + I_{1/3}(\zeta))$$

$$(2) Ai(z) = \frac{\sqrt{z/3}}{\pi} K_{1/3}(\zeta) = \frac{2^{2/3} 3^{-5/6}}{\sqrt{(\pi)}} z \exp(-\zeta) U(5/6; 5/3; 2\zeta)$$

$$(3a) Ai(-z) = \frac{\sqrt{z}}{3} (J_{-1/3}(\zeta) + J_{1/3}(\zeta))$$

$$(3b) Bi(-z) = \sqrt{\frac{z}{3}} (J_{-1/3}(\zeta) - J_{1/3}(\zeta))$$

$$(4a) Ai'(z) = \frac{z}{3} (I_{2/3}(\zeta) - I_{-2/3}(\zeta))$$

$$(4b) Bi'(z) = \frac{z}{\sqrt{3}} (I_{-2/3}(\zeta) + I_{2/3}(\zeta))$$

$$(5a) Ai'(z) = -\frac{z}{\pi\sqrt{3}} K(2/3)(\zeta) = -\frac{4^{2/3} 3^{-7/6}}{\sqrt{\pi}} z^2 \exp(-\zeta) U(7/6; 7/3; 2\zeta)$$

$$(6a) Ai'(-z) = \frac{z}{3} (J_{2/3}(\zeta) - J_{-2/3}(\zeta)),$$

$$(6b) Bi'(-z) = \frac{z}{\sqrt{3}} (J_{-2/3}(\zeta) + J_{2/3}(\zeta)),$$

The asymptotic expansions derivable from these representations and Hankel's asymptotic expansions for the Bessel functions are used for large modulus of  $z$ . The implementation has taken advantage of the error bounds given in

For small modulus of  $z$ , a rational approximation is used. This approximant is derived from

Luke, Y. L., Mathematical Functions and their Approximations, Academic Press, pp 361-363, 1975.

The identities given below are for Bessel functions of the first kind in terms of modified Bessel functions of the first kind are also used with the rational approximant.

For moderate modulus of  $z$ , three techniques are used. Two use a backward recursion algorithm with (1), (3), (4), and (6). The third uses the confluent hypergeometric representations given by (2) and (5). The backward recursion algorithm generates values of the modified Bessel functions of the first kind of orders  $+ \text{ or } - 1/3$  and  $+ \text{ or } - 2/3$  for  $z$  in the right half plane. Values for the corresponding Bessel functions of the first kind are recovered via the identities

$$J_\nu(z) = \exp(\nu\pi i/2) I_\nu(z \exp(-\pi i/2)), 0 \leq \arg(z) \leq \pi/2$$

and

$$J_\nu(z) = \exp(-\nu\pi i/2) I_\nu(z \exp(\pi i/2)), -\pi/2 \leq \arg(z) < 0.$$

The particular backward recursion algorithm used is discussed in

This function evaluates  $Ai(z)$  and  $Ai'(z)$  from their asymptotic expansions for  $|arg(-z)| < \pi/3$ . For speed, the number of terms needed to achieve about 16 decimals accuracy is tabled and determined from  $|z|$ .

#### Parameters

in	<code>__z</code>	The value at which the Airy function and its derivative are evaluated.

Compute the modified Bessel functions of the first kind of orders  $+1/3$  and  $+2/3$  needed to compute the Airy functions and their derivatives from their representation in terms of the modified Bessel functions. This function is only used for  $z$  less than two in modulus and in the closed right half plane. This stems from the fact that the values of the modified Bessel functions occurring in the representations of the Airy functions and their derivatives are almost equal for  $z$  large in the right half plane. This means that loss of significance occurs if these representations are used for  $z$  too large in magnitude. This algorithm is also not used for  $z$  too small, since a low order rational approximation can be used instead.

This routine is an implementation of a modified version of Miller's backward recurrence algorithm for computation by from the recurrence relation

$$I_{\nu-1} = (2\nu/z)I_{\nu} + I_{\nu+1}$$

satisfied by the modified Bessel functions of the first kind. the normalization relationship used is

$$\frac{z/2)^{\nu} e^z}{\Gamma(\nu+1)} = I_{\nu}(z) + 2 \sum_{k=1}^{\infty} \frac{(k+\nu)\Gamma(2\nu+k)}{k!\Gamma(1+2\nu)} I_{\nu+k}(z).$$

This modification of the algorithm is given in part in

Olver, F. W. J. and Sookne, D. J., Note on Backward Recurrence Algorithms, Math. of Comp., Vol. 26, no. 120, Oct. 1972.

And further elaborated for the Bessel functions in

Sookne, D. J., Bessel Functions I and J of Complex Argument and Integer Order, J. Res. NBS - Series B, Vol 77B, Nos. 3 & 4, July-December, 1973.

Insight was also gained from

Cody, W. J., Preliminary Report on Software for the Modified Bessel Functions of the First Kind, Argonne National Laboratory, Applied Mathematics Division, Tech. Memo. No. 357, August, 1980.

Cody implements the algorithm of Sookne for fractional order and nonnegative real argument. Like Cody, we do not change the convergence testing mechanism in any substantial way. However, we do trim the overhead by making the additional assumption that performing the convergence test for the functions of order 2/3 will suffice for order 1/3 as well. This assumption has not been established by rigorous analysis at this time. For speed the convergence tests are performed in the 1-norm instead of the usual Euclidean norm used in the complex plane using the inequality

$$|x| + |y| \leq \sqrt{2} \sqrt{x^2 + y^2}$$

#### Parameters

**8.3.2.8** `template<typename _Tp> void std::__detail::__airy_bessel_k( const std::complex<_Tp> & __z, _Tp __eps, std::complex<_Tp> & _Kp1d3, std::complex<_Tp> & _Kp2d3 )`

Compute approximations to the modified Bessel functions of the second kind of orders 1/3 and 2/3 for moderate arguments.

This routine computes

$$E_{\nu}(z) = \exp z \sqrt{2z/\pi} K_{\nu}(z), \text{ for } \nu = 1/3 \text{ and } \nu = 2/3$$

using a rational approximation given in

Luke, Y. L., Mathematical functions and their approximations, Academic Press, pp 366-367, 1975.

Though the approximation converges in  $|\arg(z)| \leq \pi$ , The convergence weakens as  $\text{abs}(\arg(z))$  increases. Also, in the case of real order between 0 and 1, convergence weakens as the order approaches 1. For these reasons, we only use this code for  $|\arg(z)| \leq 3\pi/4$  and the convergence test is performed only for order 2/3.

The coding of this function is also influenced by the fact that it will only be used for about  $2 \leq |z| \leq 15$ . Hence, certain considerations of overflow, underflow, and loss of significance are unimportant for our purpose.

#### Parameters

in	<code>__z</code>	The value for which the quantity $E_{nu}$ is to be computed. it is recommended that $abs(z)$ not be too small and that $ arg(z)  \leq 3\pi/4$ .
in	<code>__eps</code>	The maximum relative error allowable in the computed results. The relative error test is based on the comparison of successive iterates.
out	<code>__Kp1d3</code>	The value computed for $E_{+1/3}(z)$ .
out	<code>__Kp2d3</code>	The value computed for $E_{+2/3}(z)$ .

#### Note

In the worst case, say,  $z = 2$  and  $arg(z) = 3\pi/4$ , 20 iterations should give 7 or 8 decimals of accuracy.

#### 8.3.2.9 `template<typename _Tp> std::complex<_Tp> std::__detail::__airy_bi ( std::complex<_Tp> __z )`

#### 8.3.2.10 `template<typename _Tp> void std::__detail::__airy_hyperg_rational ( const std::complex<_Tp> & __z, std::complex<_Tp> & __Ai, std::complex<_Tp> & __Aip, std::complex<_Tp> & __Bi, std::complex<_Tp> & __Bip )`

This function computes rational approximations to the hypergeometric functions related to the modified Bessel functions of orders  $\nu = + - 1/3$  and  $\nu = -2/3$ . That is,  $A(z)/B(z)$ , Where  $A(z)$  and  $B(z)$  are cubic polynomials with real coefficients, approximates

$$\frac{\Gamma(\nu + 1)}{(z/2)^{\nu}} I_{\nu}(z) = {}_0F_1(; \nu + 1; z^2/4),$$

where the function on the right is a confluent hypergeometric limit function. For  $|z| \leq 1/4$  and  $|arg(z)| \leq \pi/2$ , the approximations are accurate to about 16 decimals.

For further details including the four term recurrence relation satisfied by the numerator and denominator polynomials in the higher order approximants, see

Luke, Y.L., Mathematical Functions and their Approximations, Academic Press, pp 361-363, 1975.

An asymptotic expression for the error is given as well as other useful expressions in the event one wants to extend this function to incorporate higher order approximants.

Note also that for speed and since this function is called by another, checks that are not absolutely necessary are not made.

#### Parameters

in	<code>__z</code>	The argument at which the hypergeometric given above is to be evaluated. Since the approximation is of fixed order, $ z $ must be small to ensure sufficient accuracy of the computed results.

At such points, Olver's expressions have zero denominators (and numerators) resulting in numerical problems. This routine averages results from four surrounding points in the complex plane to obtain the result in such cases.

8.3.2.183 `template<typename _Tp> std::complex<_Tp> std::__detail::__polylog_exp_asymp ( _Tp __s, std::complex<_Tp> __w )`

This function implements the asymptotic series for the polylog. It is given by

$$2 \sum_{k=0}^{\infty} \zeta(2k) w^{s-2k} / \Gamma(s-2k+1) - i\pi w^{(s-1)} / \Gamma(s)$$

for  $Re(w) \gg 1$

Don't check this against Mathematica 8. For real  $u$  the imaginary part of the polylog is given by  $Im(Li_s(e^u)) = -\pi u^{s-1} / \Gamma(s)$ . Check this relation for any benchmark that you use. The use of `evenzeta` leads to a speedup of about 1000.

$$Li_p(e^w) = Gamma(1-p)(-w)^{p-1} - A_p(w) - \sigma * B_p(w)$$
