6.2.2 Function Documentation

6.2.2.1 template<typename _Tp > __gnu_cxx::__promote<_Tp>::__type std::assoc_laguerre (unsigned int __n, unsigned int __m, _Tp __x) [inline]

Return the associated Laguerre polynomial of order `n`, degree `m`: $L_n^m(x)$.

The associated Laguerre function of real degree α, $L_n^\alpha(x)$, is defined by

Functions

- template< typename _Tp >

  Compute the Airy functions $Ai(x)$ and $Bi(x)$ and their first derivatives $Ai'(x)$ and $Bi(x)$ respectively.
- template< typename _Tp >
  void __airy (const std::complex< _Tp > &__z, _Tp __eps, std::complex< _Tp > &_Ai, std::complex< _Tp > &_Aip, std::complex< _Tp > &_Bi, std::complex< _Tp > &_Bip)

- template< typename _Tp >
  void __airy_asymp_absarg_lt_pio3 (std::complex< _Tp > __z, std::complex< _Tp > &_Ai, std::complex< _Tp > &_Aip)

  This function evaluates $Ai(z)$ and $Ai'(z)$ from their asymptotic expansions for $|arg(-z)| < pi/3$. For speed, the number of terms needed to achieve about 16 decimals accuracy is tabled and determined from $|z|$.
- template< typename _Tp >

- template< typename _Tp >
  void __airy_bessel_k (const std::complex< _Tp > &__z, _Tp __eps, std::complex< _Tp > &_Kp1d3, std↩::complex< _Tp > &_Kp2d3)

  Return the complex Airy Bi function.
- template< typename _Tp >
  void __airy_hyperg_rational (const std::complex< _Tp > &__z, std::complex< _Tp > &_Ai, std::complex< _Tp > &_Aip, std::complex< _Tp > &_Bi, std::complex< _Tp > &_Bip)

This function computes rational approximations to the hypergeometric functions related to the modified Bessel functions of orders $\nu = +-1/3$ and $\nu + -2/3$. That is, $A(z)/B(z)$, Where $A(z)$ and $B(z)$ are cubic polynomials with real coefficients, approximates

$$\frac{\Gamma(\nu+1)}{(z/2)^n u} I_\nu(z) =_0 F_1(;\nu+1;z^2/4),$$

where the function on the right is a confluent hypergeometric limit function. For $|z| <= 1/4$ and $|arg(z)| <= pi/2$, the approximations are accurate to about 16 decimals.

This function computes the Airy function $Ai(z)$ and its first derivative in the complex z-plane.

The algorithm used exploits numerous representations of the Airy function and its derivative. The representations are recorded here for reference:

$$(1a)Ai(z) = \frac{\sqrt{z}}{3}(I_{-1/3}(\zeta) - I_{1/3}(\zeta))$$
$$(1b)Bi(z) = \sqrt{\frac{z}{3}}(I_{-1/3}(\zeta) + I_{1/3}(\zeta))$$

$$(2)Ai(z) = \frac{\sqrt{z/3}}{\pi}K_{1/3}(\zeta) = \frac{2^{2/3}3^{-5/6}}{\sqrt{(\pi)}}z\exp(-\zeta)U(5/6;5/3;2\zeta)$$

$$(3a)Ai(-z) = \frac{\sqrt{z}}{3}(J_{-1/3}(\zeta) + J_{1/3}(\zeta))$$
$$(3b)Bi(-z) = \sqrt{\frac{z}{3}}(J_{-1/3}(\zeta) - J_{1/3}(\zeta))$$

$$(4a)Ai'(z) = \frac{z}{3}(I_{2/3}(\zeta) - I_{-2/3}(\zeta))$$
$$(4b)Bi'(z) = \frac{z}{\sqrt{3}}(I_{-2/3}(\zeta) + I_{2/3}(\zeta))$$

$$(5a)Ai'(z) = -\frac{z}{\pi\sqrt{(3)}}K_(2/3)(zeta) = -\frac{4^{2/3}3^{-7/6}}{\sqrt{(\pi)}}z^2\exp(-\zeta)U(7/6;7/3;2\zeta)$$

$$(6a)Ai'(-z) = \frac{z}{3}(J_{2/3}(\zeta) - J_{-2/3}(\zeta)),$$
$$(6b)Bi'(-z) = \frac{z}{\sqrt{3}}(J_{-2/3}(\zeta) + J_{2/3}(\zeta)),$$

Where $\zeta = -\frac{2}{3}z^{3/2}$ and $U(a;b;z)$ is the confluent hypergeometric function defined in

The asymptotic expansions derivable from these representations and Hankel's asymptotic expansions for the Bessel functions are used for large modulus of z. The implementation has taken advantage of the error bounds given in

For small modulus of z, a rational approximation is used. This approximant is derived from

Luke, Y. L., Mathematical Functions and their Approximations, Academic Press, pp 361-363, 1975.

The identities given below are for Bessel functions of the first kind in terms of modified Bessel functions of the first kind are also used with the rational approximant.

For moderate modulus of z, three techniques are used. Two use a backward recursion algorithm with (1), (3), (4), and (6). The third uses the confluent hypergeometric representations given by (2) and (5). The backward recursion algorithm generates values of the modified Bessel functions of the first kind of orders + or - 1/3 and + or - 2/3 for z in the right half plane. Values for the corresponding Bessel functions of the first kind are recovered via the identities

$$J_\nu(z) = exp(\nu\pi i/2)I_\nu(zexp(-\pi i/2)), 0 <= arg(z) <= \pi/2$$

and

$$J_\nu(z) = exp(-\nu\pi i/2)I_\nu(zexp(\pi i/2)), -\pi/2 <= arg(z) < 0.$$

The particular backward recursion algorithm used is discussed in

This function evaluates $Ai(z)$ and $Ai'(z)$ from their asymptotic expansions for $|arg(z)| < 2 * \pi/3$. For speed, the number of terms needed to achieve about 16 decimals accuracy is tabled and determined from abs(z).

Note that for the sake of speed and the fact that this function is to be called by another, checks for valid arguments are not made.

Parameters

Compute the modified Bessel functions of the first kind of orders +-1/3 and +-2/3 needed to compute the Airy functions and their derivatives from their representation in terms of the modified Bessel functions. This function is only used for z less than two in modulus and in the closed right half plane. This stems from the fact that the values of the modified Bessel functions occuring in the representations of the Airy functions and their derivatives are almost equal for z large in the right half plane. This means that loss of significance occurs if these representations are used for z to large in magnitude. This algorithm is also not used for z too small, since a low order rational approximation can be used instead.

This routine is an implementation of a modified version of Miller's backward recurrence algorithm for computation by from the recurrence relation

$$I_{\nu-1} = (2\nu/z)I_\nu + I_{\nu+1}$$

satisfied by the modified Bessel functions of the first kind. the normalization relationship used is

$$\frac{z/2)^\nu e^z}{\Gamma(\nu+1)} = I_\nu(z) + 2\sum_{k=1}^{\infty}\frac{(k+\nu)\Gamma(2\nu+k)}{k!\Gamma(1+2\nu)}I_{\nu+k}(z).$$

This modification of the algorithm is given in part in

Olver, F. W. J. and Sookne, D. J., Note on Backward Recurrence Algorithms, Math. of Comp., Vol. 26, no. 120, Oct. 1972.

And further elaborated for the Bessel functions in

Sookne, D. J., Bessel Functions I and J of Complex Argument and Integer Order, J. Res. NBS - Series B, Vol 77B, Nos. 3 & 4, July-December, 1973.

Insight was also gained from

Cody, W. J., Preliminary Report on Software for the Modified Bessel Functions of the First Kind, Argonne National Laboratory, Applied Mathematics Division, Tech. Memo. No. 357, August, 1980.

Cody implements the algorithm of Sookne for fractional order and nonnegative real argument. Like Cody, we do not change the convergence testing mechanism in any substantial way. However, we do trim the overhead by making the additional assumption that performing the convergence test for the functions of order 2/3 will suffice for order 1/3 as well. This assumption has not been established by rigourous analysis at this time. For the sake of speed the convergence tests are performed in the 1-norm instead of the usual Euclidean norm used in the complex plane using the inequality

$$|x| + |y| <= \sqrt(2)\sqrt(x^2 + y^2)$$

Parameters

in	*__z*	The argument of the modified Bessel functions.
in	*__eps*	The maximum relative error required in the results.
out	*_Ip1d3*	The value of $I_(+ 1/3)(z)$.
out	*_Im1d3*	The value of $I_(- 1/3)(z)$.
out	*_Ip2d3*	The value of $I_(+ 2/3)(z)$.

7.3.2.8 template< typename _Tp > void std::__detail::__airy_bessel_k (const std::complex< _Tp > & *__z*, _Tp *__eps*, std::complex< _Tp > & *_Kp1d3*, std::complex< _Tp > & *_Kp2d3*)

Compute approximations to the modified Bessel functions of the second kind of orders 1/3 and 2/3 for moderate arguments.

This routine computes

$$E_\nu(z) = \exp z\sqrt{2z/\pi}K_\nu(z), for\nu = 1/3 and\nu = 2/3$$

using a rational approximation given in

Luke, Y. L., Mathematical functions and their approximations, Academic Press, pp 366-367, 1975.

Though the approximation converges in $|\arg(z)| <= pi$, The convergence weakens as abs(arg(z)) increases. Also, in the case of real order between 0 and 1, convergence weakens as the order approaches 1. For these reasons, we only use this code for $|\arg(z)| <= 3pi/4$ and the convergence test is performed only for order 2/3.

The coding of this function is also influenced by the fact that it will only be used for about $2 <= |z| <= 15$. Hence, certain considerations of overflow, underflow, and loss of significance are unimportant for our purpose.

Parameters

in	*__z*	The value for which the quantity E_nu is to be computed. it is recommended that abs(z) not be too small and that $\|\arg(z)\| <= 3pi/4$.
in	*__eps*	The maximum relative error allowable in the computed results. The relative error test is based on the comparison of successive iterates.
out	*_Kp1d3*	The value computed for $E_{+1/3}(z)$.
out	*_Kp2d3*	The value computed for $E_{+2/3}(z)$.

Note

In the worst case, say, $z = 2$ and $\arg(z) = 3pi/4$, 20 iterations should give 7 or 8 decimals of accuracy.

7.3.2.10 template<typename _Tp > void std::__detail::__airy_hyperg_rational (const std::complex< _Tp > & *__z,* std::complex< _Tp > & *_Ai,* std::complex< _Tp > & *_Aip,* std::complex< _Tp > & *_Bi,* std::complex< _Tp > & *_Bip*)

This function computes rational approximations to the hypergeometric functions related to the modified Bessel functions of orders $\nu = + - 1/3$ and $\nu + -2/3$. That is, $A(z)/B(z)$, Where $A(z)$ and $B(z)$ are cubic polynomials with real coefficients, approximates

$$\frac{\Gamma(\nu+1)}{(z/2)^n u} I_\nu(z) =_0 F_1(;\nu+1;z^2/4),$$

where the function on the right is a confluent hypergeometric limit function. For $|z| <= 1/4$ and $|arg(z)| <= pi/2$, the approximations are accurate to about 16 decimals.

For further details including the four term recurrence relation satisfied by the numerator and denominator poly- nomials in the higher order approximants, see

Luke, Y.L., Mathematical Functions and their Approximations, Academic Press, pp 361-363, 1975.

An asymptotic expression for the error is given as well as other useful expressions in the event one wants to extend this function to incorporate higher order approximants.

Note also that for the sake of speed and the fact that this function will be driven by another, checks that are not absolutely necessary are not made.

Parameters

in	*__z*	The argument at which the hypergeometric given above is to be evaluated. Since the approximation is of fixed order, $\|z\|$ must be small to ensure sufficient accuracy of the computed results.

out	_Ai	The Airy function $Ai(z)$.
out	_Aip	The Airy function derivative $Ai'(z)$.
out	_Bi	The Airy function $Bi(z)$.
out	_Bip	The Airy function derivative $Bi'(z)$.

7.3.2.181 template<typename _Tp , typename ArgType > __gnu_cxx::__promote_num_t<std::complex<_Tp>, ArgType> std::__detail::__polylog_exp (_Tp *__s*, ArgType *__w*)

This is the frontend function which calculates $Li_s(e^w)$ First we branch into different parts depending on the properties of s. This function is the same irrespective of a real or complex w, hence the template parameter ArgType.

Note

: I *really* wish we could return a variant<Tp, std::complex<Tp>>.

Parameters

__s	The real order.
__w	The real or complex argument.

Returns

The real or complex value of Li_s(e^w).

7.3.2.182 template< typename _Tp > std::complex<_Tp> std::__detail::__polylog_exp_asymp (const _Tp __s, std::complex< _Tp > __w)

This function implements the asymptotic series for the polylog. It is given by

$$2\sum_{k=0}^{\infty}\zeta(2k)w^{s-2k}/\Gamma(s-2k+1)-i\pi w^(s-1)/\Gamma(s)$$

for $Re(w) >> 1$

Don't check this against Mathematica 8. For real u the imaginary part of the polylog is given by $Im(Li_s(e^u)) = -\pi u^{s-1}/\Gamma(s)$ Check this relation for any benchmark that you use. The use of evenzeta leads to a speedup of about 1000.

7.3.2.189 template<typename _Tp , int __sigma> std::complex<_Tp> std::__detail::__polylog_exp_neg_even (unsigned int __n, std::complex< _Tp > __w)

This function treats the cases of negative integer index s which are multiples of two.

In that case the sine occuring in the expansion occasionally takes on the value zero. We use that to provide an optimized series for p = 2n:

In the template parameter sigma we transport whether $p = 4k(sigma = 1)$ or $p = 4k + 2(sigma = -1)$

$$Li_p(e^w) = Gamma(1-p)(-w)^{p-1} - A_p(w) - \sigma * B_p(w)$$

This is suitable for $|w| < 2\pi$ The original series is (This might be worthwhile if we use the already present table of the Bernoullis)

$$Li_p(e^w) = \Gamma(1-p)(-w)^{p-1} - \sigma(2\pi)^p/pi\sum_{k=0}^{\infty}\Gamma(2+2k-p)/(2k+1)!(-1)^k(w/2\pi)^(2k+1)\zeta(2+2k-p)$$

This function treats the cases of negative integer index s which are odd.

In that case the sine occuring in the expansion occasionally vanishes. We use that to provide an optimized series for $p = 1+2k$: In the template parameter sigma we transport whether $p = 1+4k(sigma = 1)$ or $p = 3+4k(sigma = -1)$

$$Li_p(e^w) = \Gamma(1-p)*(-w)^{p-1} + \sigma * A_p(w) - \sigma * B_p(w)$$

with

$$A_p(w) = 2(2\pi)^(p-1)*\Gamma(1-p)(1+w^2/(4pi^2))^{-1/2+p/2}\cos((1-p)ArcTan(2pi/w))$$

and

$$B_p(w) = 2(2pi)^(p-1)*\sum_{k=0}^{\infty}\Gamma(1+2k-p)/(2k)!(-w^2/4/\pi^2)^k(\zeta(1+2k-p)-_T p1)$$

This is suitable for $|w| < 2\pi$. The use of evenzeta gives a speedup of about 50 The original series is (This might be worthwhile if we use the already present table of the Bernoullis)

At such points, Olver's expressions have zero denominators (and numerators) resulting in numerical problems. This routine averages results from four surrounding points in the complex plane to obtain the result in such cases.
